

ABSTRACT OF THE DISCLOSURE

Inputs of a control circuit are connected to a terminal to which an external operation control signal is supplied and a terminal to which a timing signal used exclusively for testing is supplied, and the control circuit is made controllable such that, in a test mode, a state of an internal operation control signal is changed in response to a change of a state of the external operation control signal, and the internal operation control signal is changed in response to the timing exclusively used for testing, whereas, in a normal operation mode, the state of the internal operation control signal is changed in response to the change of the state of the external operation control signal, and the internal operation control signal is changed in response to the change of the external operation control signal.
